

Endpoint polynomial construction: finite verification, not a neural training result

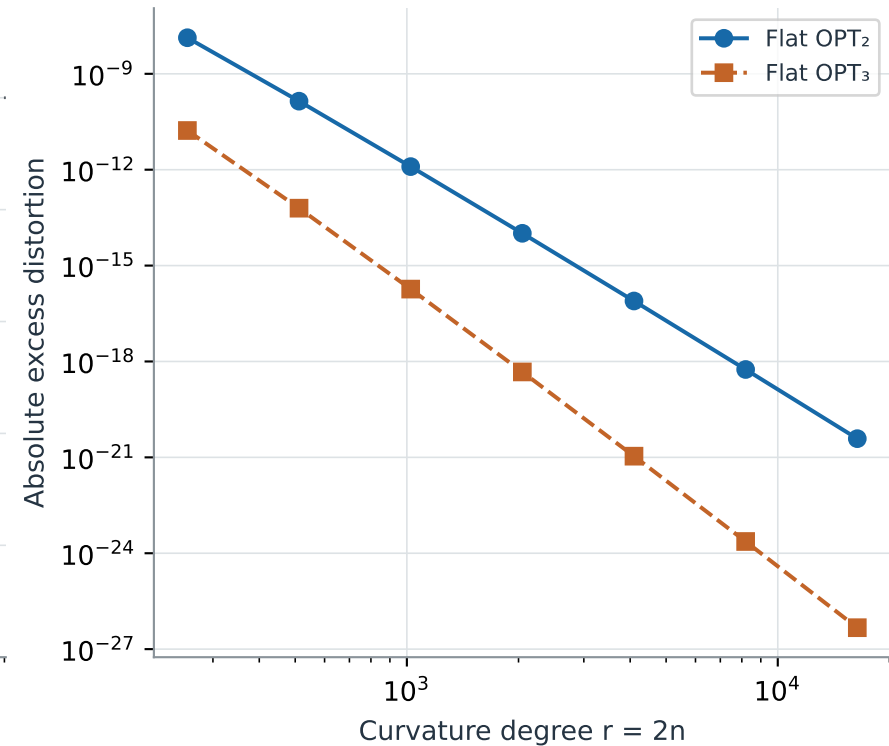

Unequal source weights

Finite-degree scaling check

Normalization: $0 < \varphi'' \leq 1$

Seven constructed instances; all 18 deterministic hierarchies enumerated. Bounds use numerical costs, not interval arithmetic.
 $\delta = (4 \log n / n)^2$; points $(0, 2\delta, 1-2\delta, 1)$; masses $(1/2-\delta^2, \delta^2, \delta^2, 1/2-\delta^2)$.
